

x86 Instruction Encoding (12.3)

Outlines

- Introduction
- Instruction Format
- Single Byte Instructions
- Move Immediate to Register
- Register Mode Instructions
- Processor Operand-Size Prefix
- Memory Mode Instructions

Introduction

- The Intel 8086 processor was the first in a line of processors using a ***Complex Instruction Set Computer*** (CISC) design.
 - a wide variety of memory-addressing, shifting, arithmetic, data movement, and logical operations.
- To *encode* an instruction means to convert an assembly language instruction and its operands into machine code.
- To *decode* an instruction means to convert a machine code instruction into assembly language.
- We will begin with the 8086/8088 processor as an illustrative example.
 - Later, we will show some of the changes made when Intel introduced 32-bit processors.

Instruction Format

Instruction Prefix	Opcode	ModR/M	SIB	Address Displacement	Immediate Data
1 byte	1-3 bytes	1 byte	1 byte	1-4 bytes	1-4 bytes

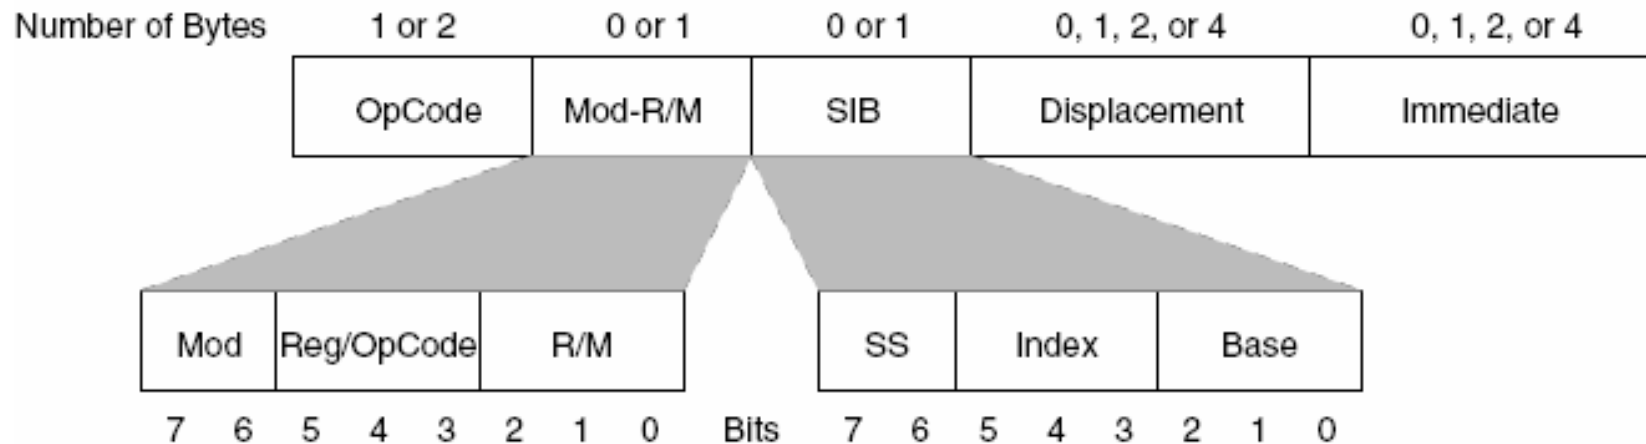

- Instructions are stored in little-endian order, so the prefix byte is located at the instruction's starting address.
- Every instruction has an opcode, but the remaining fields are optional.
- Most instructions are 2 or 3 bytes.

-
- The **instruction prefix** overrides default operand sizes. The prefix byte is **not** the *opcode expansion prefix* discussed earlier - they are special bytes to modify the behavior of existing instruction
 - The **opcode** (operation code) identifies a specific variant of an instruction.
 - E.g. the ADD instruction has nine different opcodes, depending on the parameter types used.
 - The **Mod R/M** field identifies the addressing mode and operands. The notation “**R/M**” stands for ***register*** and ***mode***.
 - The **scale index byte** (SIB) is used to calculate offsets of array indexes.
 - The **address displacement** field holds an operand’s offset, or it can be added to base and index registers in addressing modes such as *base-displacement* or *base-index-displacement*
 - The **immediate data** field holds constant operands

Another view of the x86 instruction format:

Number of Bytes	0 or 1	0 or 1	0 or 1	0 or 1
	Instruction prefix	Address-size prefix	Operand-size prefix	Segment override

(a) Optional instruction prefixes

(b) General instruction format

- The six-bit opcode identifies the operation. The same opcode is used for both 8- and 16-bit operations.
- The size of the operands is given by the **W** bit: $W = 0$ means 8-bit data and $W = 1$ means 16-bit (or 32 bits) data.
- Bit number one, marked **D**, specifies the direction of the data transfer:
 - If **d = 0** then the destination operand is a memory location (not in reg mod), e.g.
 e.g. `add [ebx], al`
 - If **d = 1** then the destination operand is a register (not in reg mod), e.g.
 e.g. `add al, [ebx]`
- the **D** bit specifies whether the register in the **REG** field is a source or destination operand, **D = 0** means source and **D = 1** means destination.

- The **MODR/M** byte (byte 2 above) specifies instruction operands and their addressing mode
- The **R/M field**, combined with **MOD**, specifies either
 - the second operand in a two-operand instruction, or
 - the only operand in a single-operand instruction like NOT or NEG.
 - These two are used to let the CPU know if there is some memory operand, if yes, then how to calculate its offset address.

- The **MOD** field specifies x86 addressing mode
- **MOD = 11** means register mode.
- **MOD = 00** means memory mode with no displacement.
 - (Except when R/M= 110, then a 16-bit displacement follows).
- **MOD= 01** means memory, with 8 bit displacement following (**D8**).
- **MOD = 10** means memory mode with 16-bit displacement following (**D16**).

MOV [ESI+01234Fh], BX ; MOD 1 0

- The **REG** field specifies source or destination **register**.
- For certain (often single-operand or immediate-operand) instructions, the **REG** field may contain an *opcode extension* rather than the register bits.
- The **R/M** field will specify the operand in such case.
- Depending on the instruction, this can be either the source or the destination operand

REG Value	Register if data size is eight bits (W = 0)	Register if data size is 16-bits (W = 1)
000	al	ax
001	cl	cx
010	dl	dx
011	bl	bx
100	ah	sp
101	ch	bp
110	dh	si
111	bh	di

CODE	EXPLANATION
00	Memory Mode, no displacement follows*
01	Memory Mode, 8-bit displacement follows
10	Memory Mode, 16-bit displacement follows
11	Register Mode (no displacement)

*Except when R/M = 110, then 16-bit displacement follows

Converting Assembly Language Instructions to Machine Code

(1 bit) Direction. 1 = Register is Destination, 0 = Register is source.

An instruction can be coded with 1 to 6 bytes

Byte 1 contains three kinds of information:

- Opcode field (6 bits) specifies the operation such as add, subtract, or move
- Register Direction Bit (D bit)
 - Tells the register operand in REG field in byte 2 is source or destination operand
 - 1: Data flow to the REG field from R/M
 - 0: Data flow from the REG field to the R/M
- Data Size Bit (W bit)
 - Specifies whether the operation will be performed on 8-bit or 16-bit data
 - 0: 8 bits
 - 1: 16 bits

Byte 2 has two fields:

- Mode field (MOD) – 2 bits
- Register field (REG) – 3 bits
- Register/memory field (R/M field) – 2 bits

101	CH	BP
110	DH	SI
111	BH	DI

Register-Mode Instructions

- In instructions using register operands, the **Mod R/M** byte contains a 3-bit identifier for each register operand.
- Bits 6 to 7 are the *mod* field, which identifies the addressing mode.
- Bits 3 to 5 are the *reg* field, which identifies the source operand.
- Bits 0 to 2 are the *r/m* field, which identifies the destination operand.

e.g.

ADD CX, AX

= 00000001 11 000 001

= **01C1** h

Memory Mode Instructions

- Intel assembly language has a wide variety of memory addressing modes, causing the encoding of the Mod R/M byte to be fairly complex.
- Exactly 256 different combinations of operands can be specified by the Mod R/M byte.

Memory Mode Instructions

- The two bits in the **Mod** column indicate groups of addressing modes.
 - Mod 00, for example, has eight possible **R/M** values (000 to 111 binary) that identify operand types listed in the **Effective Address** column.

• Encode :

1. **MOV AX, [SI] ;**

2. **MOV [SI], AL**

Encoding of registers used in indirect addressing modes

<i>Codes</i>	<i>registers</i>
000	[BX + SI]
001	[BX + DI]
010	[BP + SI]
011	[BP + DI]
100	[SI]
101	[DI]
110	[BP]
111	[BX]

Table 12-19 16-Bit R/M Field Values
(for Mod = 10).

R/M	Effective Address
000	$[BX + SI] + D16^a$
001	$[BX + DI] + D16$
010	$[BP + SI] + D16$
011	$[BP + DI] + D16$
100	$[SI] + D16$
101	$[DI] + D16$
110	$[BP] + D16$
111	$[BX] + D16$

^aD16 indicates a 16-bit displacement.

111	(BX)	$(BX) + D8$	$(BX) + D16$

1. Provide opcodes for the following MOV instructions:

```
.data
myByte BYTE ?
myWord WORD ?
.code
mov ax,@data
mov ds,ax           ; a.
mov ax,bx           ; b.
mov bl,al           ; c.
mov al,[si]         ; d.
mov myByte,al       ; e.
mov myWord,ax       ; f.
```

2. Provide Mod R/M bytes for the following MOV instructions:

```
.data
array WORD 5 DUP(?)
.code
mov ax,@data
mov ds,ax           ; a.
mov dl,bl           ; b.
mov bl,[di]         ; c.
mov ax,[si+2]       ; d.
mov ax,array[si]    ; e.
mov array[di],ax    ; f.
```

‘Mod r/m’ Byte	Mod Register r/m	Remarks
D1	11 010 001	No operand in memory.
8E	10 001 110	One operand in memory; offset = one word displacement + contents of register BP.
0C		
1E		
18		
C2		
17		
91		

Single-Byte Instructions

- The simplest type of instruction is one with either no operand or an implied operand. Such instructions require only the opcode field, the value of which is predetermined by the processor's instruction set.

Instruction	Opcode
AAA	37
AAS	3F
CBW	98
LODSB	AC
XLAT	D7
INC DX	42

- register increments are optimized for code size and execution speed

Single Immediate Data

- When the only operand of an instruction is an immediate data the machine language code is the opcode followed by that immediate data.
- E.g. **RET 8** is **C2 08 00**, where C2 is the opcode and 0008 is the immediate data (appended in little endian order).
- E.g.

PUSH 17097Ch

50 <- 7C 09 17

= 50 7C091700 50: Opcode Byte Data Bytes: 7C091700

Single Operand (in a register) Instructions

- The machine language instruction can be obtained by adding to the register number to the opcode byte.
- **Example: *PUSH CX*** The machine instruction is **51**. The encoding steps are as follows:
 1. The opcode for PUSH with a 16-bit register operand is **50**.
 2. The register number for CX is 1, so add 1 to 50, producing opcode **51**.

PUSH BX

50 + 03 = **53**

Register, Immediate Instructions

- Immediate operands (constants) are appended to instructions in little-endian order (lowest byte first).
- The encoding format of a MOV instruction that moves an immediate word into a register is

B8 + *rw* *dw*

- where the opcode byte value is **B8** + *rw*, indicating that a register number (0 through 7) is added to B8
- *dw* is the immediate word operand, low byte first.

MOV DL, 17 (reg, imm)

B0 + 02 <-17

= 8A 17

MOV reg/mem, imm

• **Example:** **MOV BX,1** The machine instruction is **B8 01 00** (hexadecimal). Here's how it is encoded:

1. The opcode for moving an immediate value to a 16-bit register is **B8**.
2. The register number for BX is 3, so 3 is added to B8
3. The immediate operand (0001) is appended to the instruction in little-endian order (01 , 00)

B8 + 03 <- 01 00

=66 BB 0100

ADD reg16, imm16

81

ADD BX, 7F0F

81 + 3 <- 0F7F

84 0F7F

• **Example: MOV BX, 1234h** The machine instruction is **BB 34 12**. The encoding steps are as follows:

1. The opcode for moving an immediate value to a 16-bit register is **B8**.
2. The register number for BX is 3, so add 3 to B8, producing opcode **BB**.
3. The immediate operand bytes are **34 12**.
